Clinical data continue to accumulate

VRN11: stable tumor suppression expected

Plasma concentrations continued to increase dose-dependently through 480mg. From the 160mg cohort onward, concentrations above the IC90 for major EGFR mutations were stably maintained until the next dose. Given that stable plasma concentrations have translated into strong clinical outcomes in BTK inhibitor trials, VRN11's PK data are encouraging. VRN11 continued to demonstrate high tolerability despite increasing plasma concentrations. Most adverse events were EGFR-related, while Grade 3 or higher adverse events accounted for only 3%.

Among patients with the C797S mutation treated at efficacious doses of ≥160mg, all six patients achieved tumor shrinkage of more than 40%. Median PFS was 11 months, with the potential to extend as the data mature. In patients with brain metastases treated at efficacious doses, intracranial lesions remained stably controlled, resulting in an iDCR of 100% and reaffirming VRN11's competitiveness in patients with central nervous system (CNS) metastases.

VRN10 confirms efficacy in NSCLC

In the early clinical trial of VRN10, all three non-small cell lung cancer (NSCLC) patients achieved a partial response (PR). Unlike in breast cancer (BC) and gastric cancer (GC), the most frequent HER2 alterations in NSCLC are tyrosine kinase domain (TKD) mutations, representing an indication where TKIs demonstrate competitive positioning compared to antibody modalities. In HER2 TKI comparisons, VRN10 exhibited superior tolerability compared to zongertinib and savabertinib. Since zongertinib faces limitations in treating central nervous system (CNS) metastases due to low blood-brain barrier (BBB) penetration, VRN10 is expected to show stronger competitiveness in CNS. This time's trial included one HER2m NSCLC patient with ECD mutation who demonstrated tumor suppression, raising expectations for broader indications than existing TKIs limited solely to TKD mutations.

Maintain BUY and target price of W450,000

We maintain BUY and target price of W450,000. We believe that high target selectivity and BBB penetration demonstrated in preclinical trials are being validated in clinical trials. While early-phase trials carry limitations such as a heavy concentration of heavily pretreated, highly heterogenous patients, we expect cohort-specific Phase 1b trials to confirm improved clinical metrics.

VRN11: Stable tumor suppression expected

Strong PK and safety despite dose escalation

Dosing has been completed through the 560mg cohort, and dosing is currently underway in the 640mg cohort. According to data presented at WCLC, plasma concentrations increased proportionally with dose through the 480mg cohort. In cohorts receiving ≥160mg, plasma concentrations remained stably above the IC90 for major EGFR mutations throughout the 24-hour dosing interval.

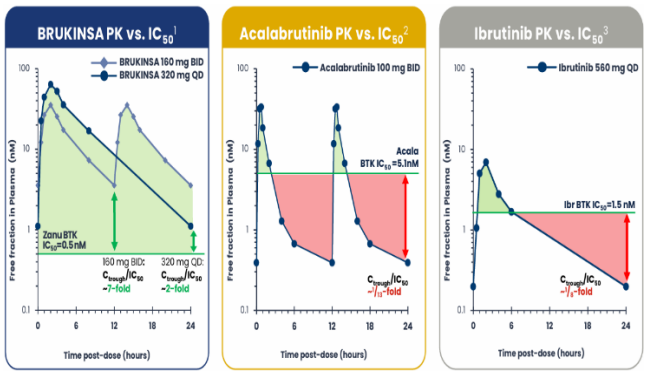

Among BTK inhibitors, zanubrutinib maintained plasma concentrations above the level required for effective BTK inhibition, unlike ibrutinib and acalabrutinib. This translated into superior progression-free survival (PFS) versus ibrutinib in clinical trials. Accordingly, VRN11's ability to maintain stable plasma concentrations is expected to translate into improved efficacy.

VRN11 PK results by dose

PK data by BTK inhibitor

Source: BeOne medicine, Yuanta Securities

Clinical comparison of BTK inhibitors

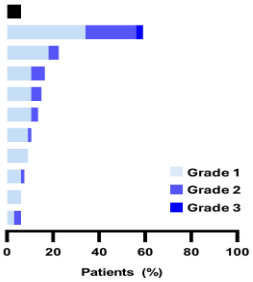

Source: BeOne medicine, Yuanta Securities

Despite plasma concentrations increasing proportionally with dose, no dose-limiting toxicity (DLT) was observed through the 480mg cohort. A total of 67 patients completed dosing at doses ranging from the Phase 1a starting dose of 10mg to 480mg. No patients discontinued treatment due to adverse events, while only 6% required dose reductions.

The most frequent adverse events were toxicities associated with EGFR inhibition, including rash (22%), pruritus (16%), and diarrhea (15%). No Grade ≥3 events were reported for these adverse events. The overall incidence of adverse events was 60%, while Grade ≥3 events occurred in only 3% of patients, reaffirming VRN11's highly favorable safety profile. Most EGFR-related adverse events occurred early in treatment and were extremely rare after five months.

100% response in C797S-mutant patients at efficacious doses

Based on the Phase 1a PK data, doses of ≥160mg appear to provide effective exposure that consistently inhibits both major EGFR mutations and the C797S resistance mutation. Six patients with the C797S mutation received doses of ≥160mg, including three patients with brain metastases.

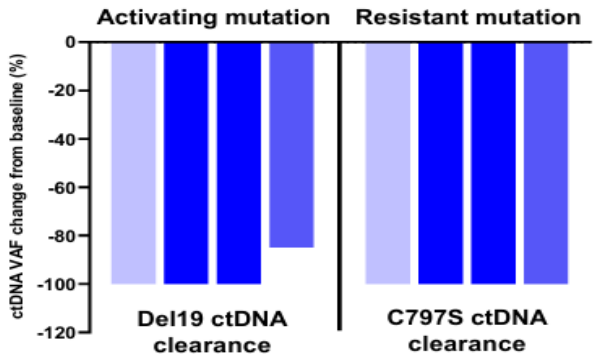

In the latest presentation, all six patients treated at efficacious doses achieved tumor shrinkage of more than 40%, exceeding the 30% threshold for a partial response. Plasma ctDNA analysis also showed complete clearance of C797S ctDNA in all four evaluable patients, while Del19 ctDNA became undetectable in three patients. Given that ctDNA clearance after treatment has been associated with favorable clinical outcomes in multiple osimertinib trials, the ctDNA clearance observed following VRN11 treatment is encouraging. Median PFS in the group of patients with C797S mutation was 11 months. However, follow-up was relatively short as of early July, leaving the data immature. The median PFS could extend further with longer follow-up.

Stable disease control in the CNS

Of the patients treated with VRN11, 32 patients (47%) had CNS metastases, including 19 patients with brain metastases who received doses of ≥160mg. High blood–brain barrier penetration is a key competitive strength of VRN11, with BBB penetration exceeding 100% in animal studies. CSF concentration analysis conducted during the clinical trial also showed that, in a patient receiving 240mg, the CSF concentration was approximately twice the plasma concentration.

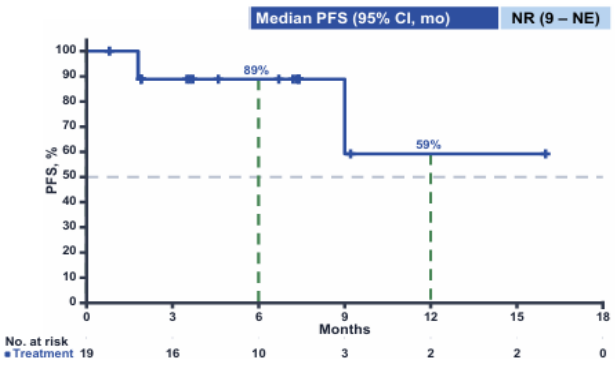

Median PFS in patients with brain metastases was 6.7 months, while intracranial median PFS had not been reached. Among the 19 patients, intracranial lesions remained stably controlled in all five patients with measurable lesions. Of the 14 patients with non-measurable lesions, intracranial lesions completely disappeared in four, while the remaining ten maintained stable disease with no change in lesion size. Accordingly, the intracranial complete response rate (iCR) and intracranial disease control rate (iDCR) were 21% and 100%, respectively.

Phase 1b/2 to evaluate detailed cohorts

The Phase 1b trial will likely evaluate five monotherapy cohorts and one chemotherapy combination cohort, testing two dose levels based on monotherapy. The 320mg dose is confirmed, and higher dose will likely be finalized based on ongoing Phase 1a results.

We believe 320mg is an appropriate dose selection as it is higher than 160mg that shows plasma concentrations sufficient to inhibit key EGFR mutations (D, L) and C797S mutations, while showing no tolerability concerns up to 480mg. As for the atypical mutation cohort to be conducted in Phase 1b, we expect the higher-dose cohort to be effective given lower inhibition against atypical EGFR mutations compared to key mutations.

The company plans to carry out one clinical trial for the chemotherapy combination cohort, raising the dose from 240mg to assess combination safety and tolerability. Combining an EGFR TKI with chemotherapy is effective in patients with pronounced tumor heterogeneity, with meaningful improvement in clinical trial indicators validated by FLAURA2 trial with osimertinib.

VRN11 clinical trial plan

Expectations for VRN10 competitiveness in NSCLC

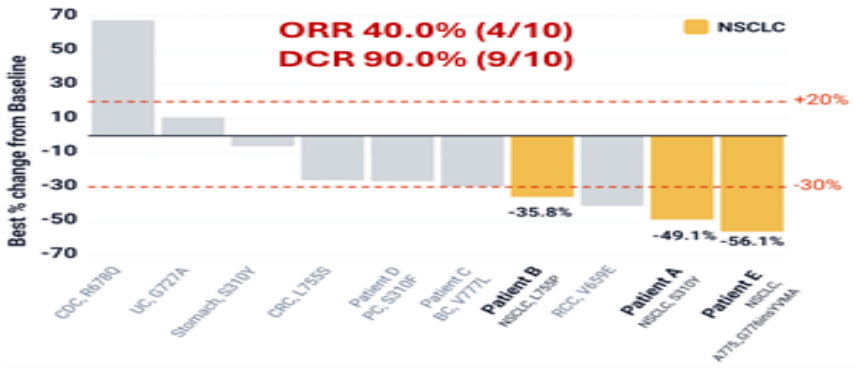

HER2m NSCLC confirms potential despite small sample size

The early-stage clinical trial for VRN10 is underway across diverse HER2-altered solid tumors, with data from 10 treated patients presented at the World Conference on Lung Cancer (WCLC). Four patients achieved a 30% or higher tumor shrinkage, delivering a 40% overall response rate (ORR). Three of the four were NSCLC patients, with all enrolled NSCLC patients exhibiting tumor regression. While constrained by the small patient cohort, the results clearly validated VRN10's clinical development viability in HER2-mutant (HER2m) NSCLC.

HER2m NSCLC accounts for 2-4% of all NSCLC cases and is primarily characterized by TKD mutations, different from BC and GC. The most prevalent alteration is the HER2 YVMA insertion within exon20, accounting for 40-60% of all HER2m NSCLC. The three NSCLC patients in the VRN10 trial had distinct variants including one ECD mutation and two TKD mutations, one of which was the YVMA insertion.

The HER2 YVMA patient had received seven prior lines of therapy before VRN10 treatment, including immune-oncology (IO), chemotherapy and even HER2 TKI (sevabertinib, ELVN-002) and T-Dxd. Although the patient developed resistance to HER2 targeted therapies, the patient achieved an encouraging result with tumor reduction of 56% in the first scan after taking VRN10. As VRN10 demonstrated tumor inhibition even in HER2 ECD mutation, we believe there is potential for indication expansion to the entire HER2m NSCLC, different from zongertinib whose NSCLC indication is confined to HER2 TKD mutations.

VRN10 initial clinical trial results

Source: WCLC, Yuanta Securities

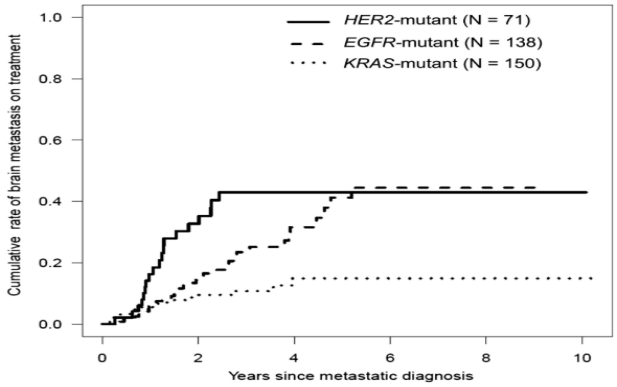

CNS efficacy, the primary competitive weapon

In cellular assays, VRN10 showed superior selectivity over wild-type EGFR (EGFR WT) across diverse HER2 mutations including HER2 WT. In benchmark comparisons with peer TKIs, its HER2 selectivity over EGFR WT outperformed savabertinib and was similar to zongertinib. In the HER2 YVMA model, the primary driver mutation in HER2m NSCLC, VRN10's IC50 came to 0.007uM, better than zongertinib (0.010uM) and savabertinib (0.014uM).

We expect VRN10 to hold a competitive edge in the targeted HER2 treatment on superior HER2 selectivity and high BBB penetration. HER2 alterations raise the risk of CNS metastases, with 19% of HER2m NSCLC patients having brain metastases at diagnosis, and 28% developing CNS metastases during therapy.

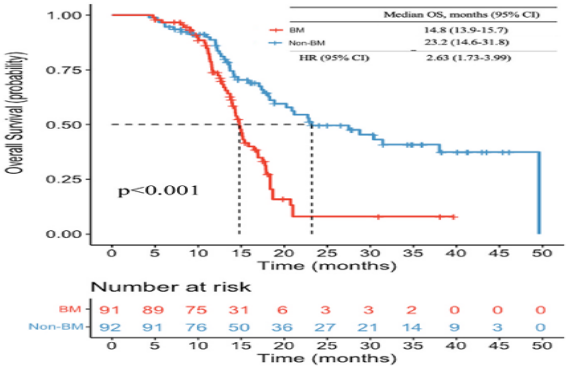

Superior BBB penetration is the biggest differentiator against zongertinib. In rat models, zongertinib showed a low Kp, uu, brain of below 0.1. In a mouse model of HER2 YVMA brain metastases, zongeritnib demonstrated inferior tumor regression effect and shorter overall survival period than VRN10.
